## **Description of Work**

The aim is to upgrade and extend a set of existing diagram catalogues and PC tools on the fundamental accuracy and stability of finite-difference methods (explicit/compact FDs and filtering). One issue is the stability and accuracy of ODE integrators, another on space discretization of wave-like solutions and the combined accuracy of spatial discretization and time integration. We are in an engineering (AE) faculty, and all is eventually about (fundamentals in hi-order) computational fluid dynamics; pure math is not the top subject. For example ODE/time integrators like implicit Runge-Kutta schemes shall be included for a simple model equation (by a PC script; first versions exist). In spatial direction, non-periodic boundary conditions may be taken into account, or methods for pseudo-discontinuities. The brief introduction at the beginning of each catalogue is so far in German but will be in English for the upgraded versions; for more information see my ResearchGate site (->publications, ->technical reports).
